Lab 4: Heart of the (Tiny) Tiger

July 10, 2020

Agenda: Writing functions to automate repetitive tasks; fitting statistical models.

The gamma distributions are a family of probability distributions defined by the density functions,

$$f(x) = \frac{x^{a-1}e^{-x/s}}{s^a\Gamma(a)}$$

where the **gamma function** $\Gamma(a) = \int_0^\infty u^{a-1} e^{-u} du$ is chosen so that the total probability of all non-negative x is 1. The parameter a is called the **shape**, and s is the **scale**. When a=1, this becomes the exponential distributions we saw in the first lab. The gamma probability density function is called **dgamma()** in R. You can prove (as a calculus exercise) that the expectation value of this distribution is as, and the variance as^2 . If the mean and variance are known, μ and σ^2 , then we can solve for the parameters,

$$a = \frac{a^2 s^2}{as^2} = \frac{\mu^2}{\sigma^2}$$
$$s = \frac{as^2}{as} = \frac{\sigma^2}{\mu}$$

In this lab, you will fit a gamma distribution to data, and estimate the uncertainty in the fit.

Our data today are measurements of the weight of the hearts of 144 cats.

Part I

1. The data is contained in a data frame called cats, in the R package MASS. (This package is part of the standard R installation.) This records the sex of each cat, its weight in kilograms, and the weight of its heart in grams. Load the data as follows:

```
library(MASS)
```

```
##
## Attaching package: 'MASS'
## The following object is masked from 'package:dplyr':
##
## select
data(cats)
summary(cats)
```

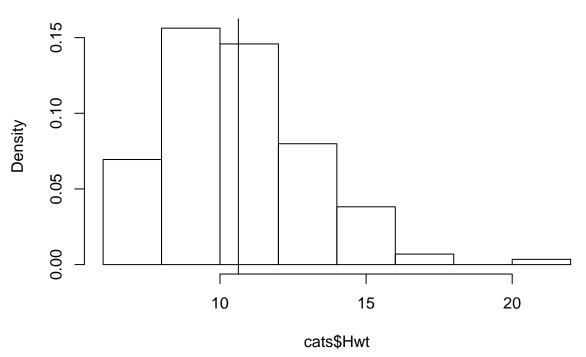

```
##
    Sex
                 Bwt
                                   Hwt
    F:47
                    :2.000
                                     : 6.30
            Min.
                             Min.
            1st Qu.:2.300
##
    M:97
                             1st Qu.: 8.95
##
            Median :2.700
                             Median :10.10
                    :2.724
                                     :10.63
##
            Mean
                             Mean
##

                             3rd Qu.:12.12
                                     :20.50
##
            Max.
                    :3.900
                             Max.
```

Run summary(cats) and explain the results.

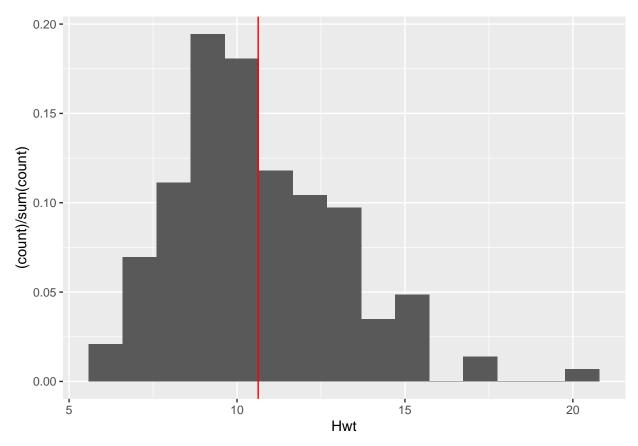

2. Plot a histogram of these heart weights using the probability=TRUE option. Add a vertical line with your calculated mean using abline(v=yourmeanvaluehere). Does this calculated mean look correct?

```
hist(cats$Hwt, probability=TRUE)
abline(v = 10.63)
```

Histogram of cats\$Hwt

```
# or using ggplot2
cats %>% ggplot(aes(x = Hwt, y = (..count..)/sum(..count..)))+
  geom_histogram(bins = 15)+
  geom_vline(aes(xintercept = 10.63), col='red')
```

3. Define two variables, fake.mean <- 10 and fake.var <- 8. Write an expression for a using these placeholder values. Does it equal what you expected given the solutions above? Once it does, write another such expression for s and confirm.

```
fake.mean <- 10
fake.var <- 8
a <- fake.mean^2/fake.var
s <- fake.var/fake.mean</pre>
```

4. Calculate the mean, standard deviation, and variance of the heart weights using R's existing functions for these tasks. Plug the mean and variance of the cats' hearts into your formulas from the previous question and get estimates of a and s. What are they? Do not report them to more significant digits than is reasonable.

```
cats.mean <- mean(cats$Hwt)
cats.std <- sd(cats$Hwt)
cats.var <- var(cats$Hwt)
a <- cats.mean^2/cats.var
s <- cats.var/cats.mean</pre>
```

5. Write a function, cat.stats(), which takes as input a vector of numbers and returns the mean and variances of these cat hearts. (You can use the existing mean and variance functions within this function.) Confirm that you are returning the values from above.

```
cat.stats <- function(vec = cats$Hwt){
  return(list(cats.mean = mean(vec), cats.var = var(vec)))
}</pre>
```

Part II

6. Now, use your existing function as a template for a new function, gamma.cat(), that calculates the mean and variances and returns the estimate of a and s. What estimates does it give on the cats' hearts weight? Should it agree with your previous calculation?

```
gamma.cat <- function(vec = cats$Hwt){
  cats.mean <- mean(vec)
  cats.var <- var(vec)
  a <- cats.mean ^ 2 / cats.var
  s <- cats.var / cats.mean
  return(list(a = a, s = s))
}</pre>
```

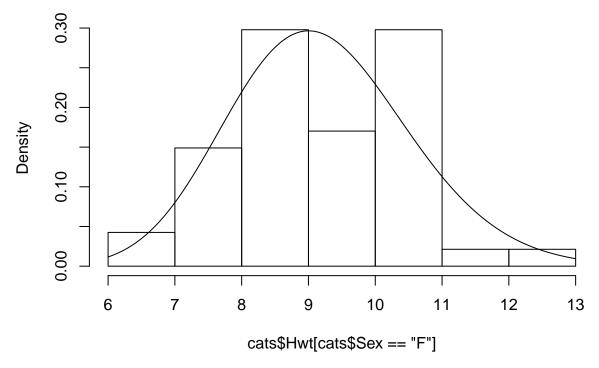

7. Estimate the a and s separately for all the male cats and all the female cats, using gamma.cat(). Give the commands you used and the results.

```
gamma.est.male <- gamma.cat(cats$Hwt[cats$Sex == 'M'])
gamma.est.female <- gamma.cat(cats$Hwt[cats$Sex == 'F'])</pre>
```

8. Now, produce a histogram for the female cats. On top of this, add the shape of the gamma PDF using curve() with its first argument as dgamma(), the known PDF for the Gamma distribution. Is this distribution consistent with the empirical probability density of the histogram?

```
hist(cats$Hwt[cats$Sex == 'F'], probability = T)
curve(dgamma(x, shape = gamma.est.female$a, scale = gamma.est.female$s), add = T)
```

Histogram of cats\$Hwt[cats\$Sex == "F"]

9. Repeat the previous step for male cats. How do the distributions compare?

```
hist(cats$Hwt[cats$Sex == 'M'], probability = T)
curve(dgamma(x, shape = gamma.est.male$a, scale = gamma.est.male$s), add = T)
```

Histogram of cats\$Hwt[cats\$Sex == "M"]
